(57) **ABSTRACT**

Methods and apparatuses for enabling electronic communication with an audibly-impaired user are disclosed. A communication device receives a call from a video endpoint associated with a calling party, wherein the call is intended for the audibly-impaired user. If the audibly-impaired user is unavailable to receive the call, information is selected from a database with one or more entries associated with the audibly-impaired user. The one or more entries include a video greeting previously recorded by the audibly-impaired user and a text greeting previously entered by the audibly-impaired user. The video greeting and the text greeting are combined as a merged video stream. The merged video stream is then presented on the video endpoint associated with the calling party.

METHODS AND APPARATUSES FOR VIDEO AND TEXT IN COMMUNICATION GREETINGS FOR THE AUDIBLY-IMPAIRED

TECHNICAL FIELD

Embodiments discussed herein relates generally to video phone communication systems, and more specifically, to methods and apparatuses for providing customized greeting in communications for audibly-impaired persons.

BACKGROUND

Traditional communication systems, such as standard and cellular telephone systems, enable verbal communications between people at different locations. Communication systems for audibly-impaired individuals (e.g., individuals with hearing impairments, speech impairments, or a combination thereof) enable non-audible communications. For example, some such communication systems enable audibly-impaired individuals to communicate using communication endpoints (e.g., video endpoints, text endpoints, etc.) configured to transmit and receive non-audible communications (e.g., video, text, etc.).

These communication endpoints are sometimes registered with entities that provide services for audibly-impaired users (e.g., communication session enabling services, user account information databases, audible to non-audible communication translation, etc.).

Some communication systems for audibly-impaired people enable communications between communication devices for audibly-impaired people and communication systems for audibly-capable users (e.g., standard telephones, cellular telephones, etc.). For example, a Video Relay Service (VRS) may provide speech to sign language translation services, and sign language to speech translation services for a communication session between a video phone for an audibly-impaired user and a traditional telephone for an audibly-capable user. In other words, the VRS may be used so an audibly-impaired user can carry on conversations with an audibly-capable person. In such systems, the audibly-impaired user will use sign language to a translator and the translator will speak what is signed to the audibly-capable user. In the other direction, the translator will listen to the audibly-capable user then sign what was spoken to the audibly-impaired user.

SUMMARY

Embodiments discussed herein include methods and apparatuses that provide customized greeting in communications for audibly-impaired users.

Embodiments of the present disclosure include a method for enabling electronic communication with an audibly-impaired user. The method includes receiving a call on a communication device from a video endpoint associated with a calling party, wherein the call is intended for the audibly-impaired user. The method also includes determining that the audibly-impaired user is unavailable to receive the call. Responsive to the determining, information is selected from a database with one or more entries associated with the audibly-impaired user, wherein the one or more entries include a video greeting previously recorded by the audibly-impaired user and a text greeting previously entered by the audibly-impaired user. The video greeting and the text greeting are

2

combined as a merged video stream and the merged video stream is presented on the video endpoint associated with the calling party.

Embodiments of the present disclosure also include a server at a relay service associated with an audibly-impaired user. The server includes processing circuitry configured to receive a call from a video endpoint associated with a calling party, wherein the call is intended for the audibly-impaired user. The processing circuitry is also configured to determine that the audibly-impaired user is unavailable to receive the call and select information from a database with one or more entries associated with the audibly-impaired user, wherein the one or more entries include a video greeting previously recorded by the audibly-impaired user and a text greeting previously entered by the audibly-impaired user. The processing circuitry is also configured to send the video greeting to the video endpoint associated with the calling party and send the text greeting to the video endpoint associated with the calling party.

Embodiments of the present disclosure further include a video endpoint associated with an audibly-impaired user. The video endpoint includes processing circuitry configured to receive a call from a video endpoint associated with a calling party. The processing circuitry is also configured to determine that the audibly-impaired user is unavailable to receive the call and select information from a database with one or more entries associated with the audibly-impaired user, wherein the one or more entries include a video greeting previously recorded by the audibly-impaired user and a text greeting previously entered by the audibly-impaired user. The processing circuitry is also configured to send the video greeting to the video endpoint associated with the calling party and send the text greeting to the video endpoint associated with the calling party.

Embodiments of the present disclosure further include a video endpoint associated with an audibly-impaired user. The video endpoint includes processing circuitry configured to record an input video greeting including gestures from the audibly-impaired user and enable the audibly-impaired user to enter an input text greeting. The processing circuitry is also configured to send the video greeting and the text greeting to a relay service associated with the audibly-impaired user.

BRIEF DESCRIPTION OF THE DRAWINGS

FIG. 1 is a simplified block diagram of a conventional audibly-impaired communication system.

FIG. 2 is a simplified block diagram of processing hardware that may be used in accordance with one or more embodiments of the invention.

FIG. 3A illustrates a simplified block diagram illustrating a relay service configured for operation with an audibly-impaired communication system and showing a calling process for an audibly-impaired user.

FIG. 3B illustrates a simplified block diagram illustrating the relay service configured for operation with an audibly-impaired communication system and showing a calling process for multiple audibly-impaired users using video endpoints.

FIGS. 4 and 5 are block diagrams illustrating entries in database.

FIG. 6 is a flow diagram of a generalized process for some embodiments of the present disclosure.

FIGS. 7A and 7B show an example user interface for selecting the type of video greeting and text greeting a user would like to create.

FIGS. 8A and 8B show an example user interface for entering a custom text greeting.

FIGS. 9A and 9B show an example user interface for recording a custom video greeting.

FIG. 10 shows an example user interface showing the combined text greeting and video greeting.

DETAILED DESCRIPTION

In the following detailed description, reference is made to the accompanying drawings which form a part hereof, and in which is shown by way of illustration specific embodiments in which the invention may be practiced. These embodiments are described in sufficient detail to enable those of ordinary skill in the art to practice the invention. It should be understood, however, that the detailed description and the specific examples, while indicating examples of embodiments of the invention, are given by way of illustration only and not by way of limitation. From this disclosure, various substitutions, modifications, additions rearrangements, or combinations thereof within the scope of the present invention may be made and will become apparent to those of ordinary skill in the art.

In accordance with common practice the various features illustrated in the drawings may not be drawn to scale. The illustrations presented herein are not meant to be actual views of any particular method, device, or system, but are merely idealized representations that are employed to describe various embodiments of the present invention. Accordingly, the dimensions of the various features may be arbitrarily expanded or reduced for clarity. In addition, some of the drawings may be simplified for clarity. Thus, the drawings may not depict all of the components of a given apparatus (e.g., device) or method. In addition, like reference numerals may be used to denote like features throughout the specification and figures.

Information and signals described herein may be represented using any of a variety of different technologies and techniques. For example, data, instructions, commands, information, signals, bits, symbols, and chips that may be referenced throughout the above description may be represented by voltages, currents, electromagnetic waves, magnetic fields or particles, optical fields or particles, or any combination thereof. Some drawings may illustrate signals as a single signal for clarity of presentation and description. It should be understood by a person of ordinary skill in the art that the signal may represent a bus of signals, wherein the bus may have a variety of bit widths and the present embodiments may be implemented on any number of data signals including a single data signal.

The various illustrative logical blocks, modules, circuits, and algorithm acts described in connection with embodiments disclosed herein may be implemented or performed with a general-purpose processor, a special-purpose processor, a Digital Signal Processor (DSP), an Application Specific Integrated Circuit (ASIC), a Field Programmable Gate Array (FPGA) or other programmable logic device, discrete gate or transistor logic, discrete hardware components, or any combination thereof designed to perform the functions described herein.

A general-purpose processor may be a microprocessor, but in the alternative, the general-purpose processor may be any processor, controller, microcontroller, or state machine suitable for carrying out processes of the present disclosure. A processor may also be implemented as a combination of computing devices, such as a combination of a DSP and a

microprocessor, a plurality of microprocessors, one or more microprocessors in conjunction with a DSP core, or any other such configuration.

A general-purpose processor may be part of a general-purpose computer, which should be considered a special purpose computer when configured to execute instructions (e.g., software code) for carrying out embodiments of the present disclosure. Moreover, when configured according to embodiments of the present disclosure, such a special-purpose computer improves the function of a general-purpose computer because, absent the present disclosure, the general-purpose computer would not be able to carry out the processes of the present disclosure. The present disclosure also provides meaningful limitations in one or more particular technical environments that go beyond an abstract idea. For example, embodiments of the present disclosure provide improvements in the technical field of recording, storing, and playing video messages as well as recording, storing, and presenting text messages.

In addition, it is noted that the embodiments may be described in terms of a process that is depicted as a flowchart, a flow diagram, a structure diagram, or a block diagram. Although a flowchart may describe operational acts as a sequential process, many of these acts can be performed in another sequence, in parallel, or substantially concurrently. In addition, the order of the acts may be re-arranged. A process may correspond to a method, a function, a procedure, a subroutine, a subprogram, etc. Furthermore, the methods disclosed herein may be implemented in hardware, software, or both. If implemented in software, the functions may be stored or transmitted as one or more instructions or code on a computer-readable medium. Computer-readable media includes both computer storage media and communication media including any medium that facilitates transfer of a computer program from one place to another.

It should be understood that any reference to an element herein using a designation such as “first,” “second,” and so forth does not limit the quantity or order of those elements, unless such limitation is explicitly stated. Rather, these designations may be used herein as a convenient method of distinguishing between two or more elements or instances of an element. Thus, a reference to first and second elements does not mean that only two elements may be employed there or that the first element must precede the second element in some manner. Also, unless stated otherwise a set of elements may comprise one or more elements.

Elements described herein may include multiple instances of the same element. These elements may be generically indicated by a numerical designator (e.g., 110) and specifically indicated by the numerical indicator followed by an alphabetic designator (e.g., 110A) or a numeric indicator preceded by a “dash” (e.g., 110-1). For ease of following the description, for the most part, element number indicators begin with the number of the drawing on which the elements are introduced or most fully discussed. Thus, for example, element identifiers on a FIG. 1 will be mostly in the numerical format 1xx and elements on a FIG. 4 will be mostly in the numerical format 4xx.

Embodiments discussed herein include methods and apparatuses that provide customized greeting in communications for audibly-impaired users. These customized greeting may include a video message, a text message, or a combination thereof.

FIG. 1 illustrates a conventional communication system 100 useful for the audibly-impaired. The communication system 100 enables an audibly-impaired user 190 (may also be referred to herein as a deaf party 390) to engage in conversa-

5

tion through the communication system **100** with an audibly-capable user **110**. The audibly-impaired user **190** may exhibit varying levels of impairment and may be a voice-capable audibly-impaired user or a voice-incapable audibly-impaired user. A communication session between the users is facilitated through the use of various types of equipment, which may be coupled together using one or more networks (**120**, **170**), which may include a telephone network such as the Public Switched Telephone Network (PSTN). Alternatively, use of the term “telephone network” as used herein also contemplates other networks that are compatible and configured to provide communications using digital standards and data packets, an example of which includes Voice Over Internet Protocol (VOIP).

To interface an audibly-impaired user into a generally voice-based communication system, interpretive services are employed allowing audibly-impaired users to communicate with a translator, such as, for example, through sign language. One means for relaying the communicative expressions of the audibly-impaired user **190** within the communication system **100** incorporates a video phone **192** for capturing and displaying the communicative expressions exhibited by the audibly-impaired user **190** and for displaying interpreted voice information originating from the audibly-capable user **110**. The expressions, such as sign language and/or body language, may be interpreted or translated by a Video Relay Service (VRS) **150**. The audibly-capable user **110** interacts in a conventional manner with the VRS **150** through a voice-based dialogue conveyed over a conventional voice phone **112** and occurring between the audibly-impaired user **190** and a translator at the VRS **150**.

FIG. 2 illustrates a computing system **200** for practicing embodiments of the present disclosure. Computer, computing system, video endpoint, mobile device, and server may be used interchangeably herein to indicate a system for using processing circuitry for practicing some embodiments of the present disclosure. The processing circuitry may be custom circuitry or may be configured for executing software programs containing computing instructions. Thus, the computing system may include one or more processors **210**, memory **220**, one or more communication elements **250**, user interface elements **230**, and storage **240**.

As non-limiting examples, the computing system **200** may be a user-type computer, a file server, a compute server, a notebook computer, a tablet, a handheld device, a mobile device, or other similar computer system for executing software.

The one or more processors **210** may be configured for executing a wide variety of operating systems and applications including the computing instructions for carrying out embodiments of the present disclosure.

The memory **220** may be used to hold computing instructions, data, and other information for performing a wide variety of tasks including performing embodiments of the present disclosure. By way of example, and not limitation, the memory **220** may include Synchronous Random Access Memory (SRAM), Dynamic RAM (DRAM), Read-Only Memory (ROM), Flash memory, and the like.

Information related to the computing system **200** may be presented to, and received from, a user with one or more user interface elements. As non-limiting examples, the user interface elements may include elements such as displays, keyboards, mice, joysticks, haptic devices, microphones, speakers, cameras, and touchscreens. A display on the computing system may be configured to present a graphical user interface (GUI) with information about some embodiments of the present disclosure, as is explained below.

6

The communication elements **250** may be configured for communicating with other devices or communication networks. As non-limiting examples, the communication elements **250** may include elements for communicating on wired and wireless communication media, such as for example, serial ports, parallel ports, Ethernet connections, universal serial bus (USB) connections IEEE 1394 (“firewire”) connections, Bluetooth wireless connections, 802.11 a/b/g/n type wireless connections, and other suitable communication interfaces and protocols.

The storage **240** may be used for storing relatively large amounts of non-volatile information for use in the computing system **200** and may be configured as one or more storage devices. By way of example, and not limitation, these storage devices may include computer-readable media (CRM). This CRM may include, but is not limited to, magnetic and optical storage devices such as disk drives, magnetic tapes, CDs (compact disks), DVDs (digital versatile discs or digital video discs), and other equivalent storage devices.

Software processes illustrated herein are intended to illustrate representative processes that may be performed by the systems illustrated herein. Unless specified otherwise, the order in which the process acts are described is not intended to be construed as a limitation, and acts described as occurring sequentially may occur in a different sequence, or in one or more parallel process streams. It will be appreciated by those of ordinary skill in the art that many steps and processes may occur in addition to those outlined in flow charts. Furthermore, the processes may be implemented in any suitable hardware, software, firmware, or combinations thereof.

When executed as firmware or software, the instructions for performing the processes may be stored on a computer-readable medium. A computer-readable medium includes, but is not limited to, magnetic and optical storage devices such as disk drives, magnetic tape, CDs (compact disks), DVDs (digital versatile discs or digital video discs), and semiconductor devices such as RAM, DRAM, ROM, EPROM, and Flash memory.

By way of non-limiting example, computing instructions for performing the processes may be stored on the storage **240**, transferred to the memory **220** for execution, and executed by the processors **210**. The processors **210**, when executing computing instructions configured for performing the processes, constitutes structure for performing the processes and can be considered a special-purpose computer when so configured. In addition, some or all portions of the processes may be performed by hardware specifically configured for carrying out the processes.

The computing system **200** may be used for the video endpoints, servers, and computers, computing devices, processing devices, and communication devices described herein with varying levels of optional components.

Generally, when discussing calls, they are referred to from the deaf user’s perspective. Thus, an “incoming call” is from an audibly-capable user to an audibly-impaired user and an “outgoing call” is from an audibly-impaired user to an audibly-capable user. Moreover, embodiments of the present disclosures support audibly-impaired user to audibly-impaired user communications. Thus, an incoming call may be from an audibly-impaired user and an outgoing call may be to an audibly-impaired user.

FIG. 3A illustrates a simplified block diagram illustrating a relay service **350** configured for operation with an audibly-impaired communication system and showing a calling process for an audibly-impaired user **390**. The relay service **350** may include a variety of services such as providing access to, and maintenance of, databases **388** associated with the audi-

bly-impaired user. In some embodiments, a Video Relay Service (VRS) may be included for the audibly-impaired user. Thus, when referring to the relay service 350, it may include servers for providing access to services and databases 388 for the audibly-impaired user 390, provide VRS services, or combinations thereof as will be apparent from the context of the discussions below.

The communication system 300 includes one or more audibly-impaired communication systems 392 (one system shown in FIG. 3 for clarity), one or more voice-capable communication systems (312 and 322) and a relay service 350.

The audibly-capable user 310, 320 may use voice-capable equipment 312, 322 to communicate with the relay service 350 through voice-capable connections 316, 326 to a voice-capable network 302. The audibly-impaired user 390 may use the video-capable equipment 392 (also referred to herein as a video endpoint 392) to communicate with the relay service 350 through a video-capable network 370.

As used herein, voice-capable networks 302 and voice-capable equipment 312, 322 means networks and equipment that can process, convey, reproduce, or a combination thereof, sounds in the auditory frequencies as analog signals, digital signals or a combination thereof. As non-limiting examples, such equipment includes conventional telephones, conventional cellular telephones, and conventional computers or handheld devices with microphone and speaker type capabilities. As non-limiting examples, such networks include a telephone network such as the Public Switched Telephone Network (PSTN) and other networks that are compatible and configured to provide communications using digital standards and data packets, an example of which includes Voice Over Internet Protocol (VOIP).

As used herein, video-capable networks 370 and video-capable equipment 392 means networks and equipment that can process, convey, reproduce, or a combination thereof, multi-frame images. As non-limiting examples, such equipment includes conventional cellular telephones with video capability, and conventional computers or handheld devices with camera and display type capabilities. As non-limiting examples, such networks include cellular networks, WiFi networks, wide area networks, hard wired networks and other private data networks configured to provide communications using digital standards and data packets. To facilitate the enhanced bandwidth needs of video phones 392, the video-capable network 370 may be implemented as a high bandwidth network such as a DSL, Cable, Ethernet, or other enhanced-bandwidth networking technology.

Wireless networks may include any network using wireless electromagnetic signals, such as, for example, Wi-Fi, cellular phone networks, bluetooth, Zigbee, and near-field communication, that is capable of carrying information including at least audio signals and in some embodiments video signals.

In general, most video-capable networks 370 would be considered to also be voice-capable networks 302 and most video-capable equipment 392 would also be considered to be voice-capable equipment 312, 322.

Within the relay service 350, a call distribution system 360 may be included to answer calls from audibly-capable users 310, 320 through calling connections 316, 326 and route them to translators 330 (only one shown in FIG. 3 for clarity), place the calls in a queue 368, or provide a customized greeting if the audibly-impaired user 390 is not available to take calls. The incoming calls include a calling connection indicator such as, for example, a telephone number, an Internet Protocol (IP) address, a website address, or other unique indicator that indicates how the connection is made and from where the connection is made.

The call distribution system 360 may also query a profile system 380 to determine information about the audibly-capable user 310, 320 placing the call in response to the calling connection indicator. The profile system 380 may access a database 400 including contact storage 388 to obtain the information about the user placing the call, such as, for example one or more customized greetings identified with the audibly-capable user 310, 320 placing the call, the audibly-impaired user 390 receiving the call, or a combination thereof. The greeting information may be retrieved and sent to the audibly-capable user.

When the audibly-impaired user is not available, the relay service 350 may include a customized greeting to be played to a caller in lieu of a connection to the caller. This customized greeting may include a video greeting, a text greeting, or a combination thereof, for presentation on a video display of the caller.

As non-limiting examples, if the audibly-capable user 310, 230 is in the deaf user's contact list 400, the database may include a custom greeting tailored to that specific contact. Otherwise, the audibly-impaired user 390 may have a default greeting to use in the case where the call comes from someone not in the contact list or only the default greeting is enabled.

The database 400 maintained at the VRS 350 may be created, modified and updated by the audibly-impaired user 390 through a network connection 394 to the profile system 380 in the relay service 350. This network connection 394 may be any suitable network, such as for example the Internet, the voice-capable network 302, or the video-capable network 370. The network connection 394 may also include tools such as web pages for viewing, updating and managing a phone book (i.e., database 400) by and for the audibly-impaired user 390. This phone book may include tools for managing greetings as explained more fully.

FIG. 3B illustrates a simplified block diagram illustrating the relay service 350 configured for operation with an audibly-impaired communication system and showing a calling process for multiple audibly-impaired users (390A, 390B) using video endpoints (392A, 392B). In this configuration audibly-impaired users (390A, 390B) may communicate directly with each other without the need for a translator. In some embodiments, the audibly-impaired user 390A may use the video endpoint 392A to communicate through the video capable network 370 directly with the audibly-impaired user 390B using the video endpoint 392B. In some cases, the connection may be made without any communication with the relay service 350. In other cases, the relay service 350 may be included to provide services such as the profile system 380 and access to various databases 388, which may include the contact database 400.

FIGS. 4 and 5 are block diagrams illustrating entries in the contact database 400. In the table of FIG. 4, the database 400 may be thought of as a contact list or phone book for the audibly-impaired user 390 that identifies preferred greetings for the listed contacts. As a result, each audibly-impaired user 390 would have a separate table.

As explained below, the video endpoint 392 may include a keypad, keyboard, or mouse, or other data entry device configured to enable the audibly-impaired user 390 to initiate a communication session in a conventional manner by entering the telephone number of an audibly-capable user 310, 320 or audibly-impaired user 390B. In addition, the audibly-impaired user 390 may be able to interact with the database 400 using data entry devices on the video endpoint to make changes to the database 400 through the network connection 394.

The database includes entries **410** for contacts **420** of the audibly-impaired user **390**. Each entry **410** may include a name for the contact **420**, one or more connection indicators **430** for the contact **420**, custom text greetings **440** and custom video greetings **450**. Of course, other fields (not shown) useful in a phone book type database **400** may also be included. Moreover, FIGS. **4** and **5** are simplified diagrams intended to illustrate associations between entries. The databases may be much more complex with multiple fields and the fields may include links to other fields, other entries, other databases, and other files.

When a contact **420** makes a call that is received by the VRS **350**, a calling connection indicator indicates the source of the call from the contact **420** (e.g., the cell phone number for Dad). The profile system may be used to correlate the calling connection indicator to an identified entry **410** (indicated by the dashed line to the entry for Dad) based on the connection indicators **430** associated with the identified entry **410**.

As non-limiting examples, the connection indicators **430** may include web-site addresses associated with the contact **420**, Internet Protocol (IP) addresses associated with the contact **420**, wireless phone numbers associated with the contact **420** and wire-line phone number associated with the contact **420**. A connection indicator **430** uniquely identifies a contact **420** within the database as well as a means of voice-capable connection **316**, **326** (FIG. **3**) to the VRS **350**, the audibly-impaired user **390**, and combinations thereof. For example, suppose a calling user makes a call to the audibly-impaired user **390**, the calling user can be identified in the database **400** and a customized greeting for that calling user may be presented with the audibly-impaired user **390** is unavailable to take the call. Thus, the customized greeting may include the text greeting "Hi Dad, can't come to the phone now," the video greeting in Video file **2**, or a combination thereof. The video in video file **2** may include a video of the audibly-impaired user **390** gesturing a default greeting or a specific greeting to "Dad" or any other type of other video file.

In the table of FIG. **5**, the database **400** may be thought of as a listing of non-specific customized greeting for when the audibly-impaired user **390** is unavailable. The database includes entries **460** for various default greetings that may be used. For example, the greeting on line **1** uses the text greeting "Hi, You've reached John, please leave a message" along with video file **3**. Similarly, the greeting on line **2** uses the text greeting "I am on vacation" along with video file **3**. The greeting on line **3** uses the text greeting "I am in a meeting from 1 to 2 today" along with video file **4**. More generally, the user may configure the database **400** with any number of video greetings and any number of text greetings. The text greetings and video greetings may then be combined in various ways depending on who is calling and whether the user wants to convey information such as, for example, why the user can't answer, where the user is, when the user will be back, etc. Thus, the text and video greetings may be customized in various ways for different callers and different situations such as day of the week or time of day.

While the databases **400** is illustrated as being resident on a server of the relay service **350**, the databases **400** may also be present on one or more video endpoints **392** associated with the user. Moreover, these databases at various locations may be configured to synchronize and share entries with each other, either from a user request or in the background at various times, which may be defined by the video endpoint **392**, the relay service **350** or a combination thereof.

FIG. **6** is a flow diagram of a generalized process **600** for some embodiments of the present disclosure. Reference may

also be made to FIG. **3A** through FIG. **5** when describing the process **600**. At operation **602**, the audibly-impaired user **390** records the video greeting on the video endpoint **392**. This video endpoint may be any suitable device configured for recording video and implementing embodiments of the present disclosure such as, for example, a video phone, a computer, a tablet device, or a smartphone.

At operation **604**, the video greeting is transmitted to the relay service **350** to be stored in the database **400**. This transmission may occur by the user requesting the transfer or it may be performed in the background at a specific event or time, which may be defined by the video endpoint **392**, the relay service **350**, or a combination thereof.

At operation **606**, the audibly-impaired user **390** enters a text greeting on the video endpoint **392**. This video endpoint may be any suitable device configured for enabling a user to enter text and implementing embodiments of the present disclosure such as, for example, a video phone, a computer, a tablet device, or a smartphone.

At operation **604**, the text greeting is transmitted to the relay service **350** to be stored in the database **400**. This transmission may occur by the user requesting the transfer or it may be performed in the background at a specific event or time, which may be defined by the video endpoint **392**, the relay service **350**, or a combination thereof.

While not illustrated, the audibly-impaired user **390** may record a number of video greetings and enter a number of text greetings. Moreover, the video endpoint **392** may include tools for associating the various greetings with each other, with specific contacts, and with specific situations as described above. These various associations may be sent to the relay service **350** as association indicators.

At any time that the user has recorded a video greeting, entered a text greeting, and associated them with each other, the user may preview the text greeting presented as an overlay on the video greeting such that the video greeting and text greeting are concurrently merged as a video stream to display to the user.

Sometime later, at operation **610**, a calling party places a call to the audibly-impaired user **390** at a time when the audibly-impaired user **390** is not available. The unavailability may be due to a number of different situations such as none of the user's video endpoints **392** are connected to a network, the user has specifically set that the user does not want to answer calls, or the user fails to answer the call after a predefined period of time. Thus, in some situations, the relay service **350** may determine that the audibly-impaired user **390** is unavailable. In other situations, the video endpoint **392** may determine that the audibly-impaired user **390** is unavailable.

At operation **612**, when it is determined that the audibly-impaired user **390** is unavailable, the video greeting is transmitted to the video endpoint **392** of the caller. This transmission may be performed from the relay service **350** or may be performed directly from the video endpoint **392** of the audibly-impaired user **390**.

Similarly, at operation **614**, when it is determined that the audibly-impaired user **390** is unavailable, the text greeting is transmitted to the video endpoint **392** of the caller. This transmission may be performed from the relay service **350** or may be performed directly from the video endpoint **392** of the audibly-impaired user **390**.

At operation **616**, the text greeting and the video greeting are combined by the video endpoint **392** of the caller and presented to the caller with the text greeting presented as an overlay on the video greeting such that the video greeting and text greeting appear as a merged video stream to be displayed on the display of the caller's video endpoint **392**.

11

While not illustrated, the merging of the appropriate video greeting and text greeting may be performed at different times and at different places. As one non-limiting example, the user selected video greeting and text greeting may be combined and stored on the video endpoint 392 of the audibly-impaired user 390. In such a situation, the combined video may be sent directly from the video endpoint 392 of the audibly-impaired user 390 to the video endpoint 392 of the caller. As another non-limiting example, the user selected video greeting and text greeting may be combined and stored on the relay service 350. In such a situation, the combined video may be sent directly from relay service 350 to the video endpoint 392 of the caller.

In some embodiments, the audibly-impaired user 390 may have multiple video endpoints 392. As a non-limiting example, the audibly-impaired user 390 may have a video phone at home, a computer at the office, a tablet device, and/or a mobile smartphone. Each of these devices may be reached by its own calling connection indicator such as, for example, a telephone number, an Internet Protocol (IP) address, a website address or other unique indicator that indicates how the connection is made and from where the connection is made. Moreover, the system may be configured such that a group number (i.e., calling connection indicator) may be used to reach the audibly-impaired user 390. In such a configuration, when a caller calls the group number, all of the video endpoints 392 associated with the group may be called in an attempt to reach the audibly-impaired user 390 on one of the devices. Also in this configuration, the audibly-impaired user 390 may create the video greeting on any of her video endpoints 392, create the text greeting on any of her video endpoints 392, and create the association between a video greeting and a text greeting on any of her video endpoints 392. Moreover, the association may be configured to be different such that the combined text and video that is displayed is one set if the group number is called, and different associations create different combinations for the various video endpoints 392 when a specific video endpoint 392 is called.

FIGS. 7A and 7B show an example user interface for selecting the type of video greeting and text greeting a user would like to create. As shown in FIG. 7A, the user may select a personal greeting (i.e., a video greeting), a text only greeting, a relay service specific greeting (e.g., Sorenson), or no greeting. Within the personal greeting, the user can select to record the video greeting or preview the video greeting. FIG. 7B shows a popup illustrating that the user may select that the personal greeting should include the video greeting only or should include a combination of the video greeting and the text greeting.

FIGS. 8A and 8B show an example user interface for entering a custom text greeting. FIG. 8A shows that the user has selected to enter his own text to customize the text greeting. FIG. 8B shows the text entered by the user to be used in the text greeting and/or the combination of the video greeting and the text greeting.

FIGS. 9A and 9B show an example user interface for recording a custom video greeting. FIG. 9A shows a video window that is blank and a record button that the user has just selected to begin entering the video greeting, which may include the user performing gestures to create the greeting. FIG. 9B shows the video greeting in the video window as it is being recorded and a stop button for the user to select to complete the video greeting.

FIG. 10 show an example user interface showing the combined text greeting and video greeting. In FIG. 10 this is a preview window so the user can determine if she is happy with the combination of the video greeting and the text greeting.

12

Once approved, this combination is what will be presented on the video endpoint of the calling party.

While certain illustrative embodiments have been described in connection with the figures, those of ordinary skill in the art will recognize and appreciate that embodiments encompassed by the disclosure are not limited to those embodiments explicitly shown and described herein. Rather, many additions, deletions, and modifications to the embodiments described herein may be made without departing from the scope of embodiments encompassed by the disclosure, such as those hereinafter claimed, including legal equivalents. In addition, features from one disclosed embodiment may be combined with features of another disclosed embodiment while still being encompassed within the scope of embodiments encompassed by the disclosure as contemplated by the inventors.

What is claimed is:

1. A method for enabling electronic communication with an audibly-impaired user, comprising:

receiving a call on a communication device from a video endpoint associated with a calling party, the call intended for the audibly-impaired user;
determining that the audibly-impaired user is unavailable to receive the call;

responsive to the determining, selecting information from a database with one or more entries associated with the audibly-impaired user, wherein the one or more entries include a video greeting previously recorded by the audibly-impaired user and a text greeting previously entered by the audibly-impaired user;

combining the video greeting and the text greeting as a merged video stream; and
presenting the merged video stream on the video endpoint associated with the calling party.

2. The method of claim 1, wherein the receiving, determining, selecting, and combining are performed by the communication device configured as a server at a relay service associated with the audibly-impaired user.

3. The method of claim 1, wherein the receiving, determining, selecting, and combining are performed by a video endpoint associated with the audibly-impaired user.

4. The method of claim 1, further comprising:
sending the video greeting from a relay service to the video endpoint associated with the calling party; and
sending the text greeting separately from the video greeting from the relay service to the video endpoint associated with the calling party;

wherein:

the receiving, the determining, and the selecting are performed by the relay service associated with the audibly-impaired user; and

the combining and the presenting are performed by the video endpoint associated with the calling party.

5. The method of claim 1, further comprising:
sending the video greeting from a video endpoint associated with the audibly-impaired user to the video endpoint associated with the calling party; and
sending the text greeting separately from the video greeting from the video endpoint associated with the audibly-impaired user to the video endpoint associated with the calling party;

wherein:

the receiving, the determining, and the selecting are performed by the video endpoint associated with the audibly-impaired user; and

the combining and the presenting are performed by the video endpoint associated with the calling party.

13

6. The method of claim 1, further comprising sending the merged video stream to the video endpoint associated with the calling party; and

wherein:

the receiving, the determining, the selecting, the combining, and the sending are performed by a relay service associated with the audibly-impaired user; and the presenting is performed by the video endpoint associated with the calling party.

7. The method of claim 1, further comprising sending the merged video stream to the video endpoint associated with the calling party; and

wherein:

the receiving, the determining, the selecting the combining, and the sending are performed by a video endpoint associated with the audibly-impaired user; and the presenting is performed by the video endpoint associated with the calling party.

8. The method of claim 1, wherein an association is defined by the audibly-impaired user between the video greeting and the text greeting and the association is used to select the video greeting and the text greeting from the database.

9. The method of claim 1, wherein combining the video greeting and the text greeting as the merged video stream comprises overlaying the text greeting on the video greeting.

10. A server at a relay service associated with an audibly-impaired user, the server comprising:

processing circuitry configured to:

receive a call from a video endpoint associated with a calling party, the call intended for the audibly-impaired user;

determine that the audibly-impaired user is unavailable to receive the call;

select information from a database with one or more entries associated with the audibly-impaired user, wherein the one or more entries include a video greeting previously recorded by the audibly-impaired user and a text greeting previously entered by the audibly-impaired user;

send the video greeting to the video endpoint associated with the calling party; and

send the text greeting to the video endpoint associated with the calling party separately from the video greeting.

11. The server of claim 10, wherein the processing circuitry comprises memory configured for storing computing instructions and one or more processors configured for executing the computing instructions.

12. The server of claim 10, wherein the processing circuitry is further configured to:

receive the video greeting from a video endpoint associated with the audibly-impaired user;

receive the text greeting from the video endpoint associated with the audibly-impaired user; and

add the video greeting to the database; and

add the text greeting to the database.

13. The server of claim 12, wherein the processing circuitry is further configured to:

receive an association indicator from the video endpoint associated with the audibly-impaired user;

14

associate the video greeting with the text greeting in the database such that the when selecting the information the association indicator is used as part of the selecting of the video greeting and the text greeting.

14. A video endpoint associated with an audibly-impaired user, the video endpoint comprising:

processing circuitry configured to:

receive a call from another video endpoint associated with a calling party;

determine that the audibly-impaired user is unavailable to receive the call;

select information from a database with one or more entries associated with the audibly-impaired user, wherein the one or more entries include a video greeting previously recorded by the audibly-impaired user and a text greeting previously entered by the audibly-impaired user;

send the video greeting to the video endpoint associated with the calling party; and

send the text greeting to the video endpoint associated with the calling party separately from the video greeting.

15. The video endpoint of claim 14, wherein the processing circuitry comprises memory configured for storing computing instructions and one or more processors configured for executing the computing instructions.

16. The video endpoint of claim 14, wherein the processing circuitry is further configured to:

record an input video greeting including gestures from the audibly-impaired user;

enable the audibly-impaired user to enter an input text greeting; and

send the input video greeting to a relay service associated with the audibly-impaired user separately from sending the input text greeting to the relay service.

17. The video endpoint of claim 16, wherein the processing circuitry is further configured to:

enable the audibly-impaired user to define an association indicator between the input video greeting and the input text greeting; and

send the association indicator to the relay service.

18. A video endpoint associated with an audibly-impaired user, the video endpoint comprising:

processing circuitry configured to:

record an input video greeting including gestures from the audibly-impaired user;

enable the audibly-impaired user to enter an input text greeting;

send the input video greeting to a relay service associated with the audibly-impaired user separately from sending the input text greeting to the relay service;

enable the audibly-impaired user to define an association indicator between the input video greeting and the input text greeting; and

send the association indicator to the relay service.

19. The video endpoint of claim 18, wherein the processing circuitry comprises memory configured for storing computing instructions and one or more processors configured for executing the computing instructions.
